Overview

- ✘ Motivation
- ✘ Goals
- ✘ Methodology
- ✘ Transient and equilibrium analysis of TCP versions
- ✘ Intra-protocol behavior
- ✘ Interaction of TCP versions
- ✘ Conclusion

Motivation

- ✘ Standard TCP (Reno): poor performance in high speed wide-area network environment
- ✘ High speed transport protocol proposals
 - ✘ modified congestion control
 - ✘ main principles
 - ✘ loss-based (e.g., HighSpeed TCP, Scalable TCP, BIC TCP)
 - ✘ delay-based (e.g., TCP Vegas, FAST TCP)
 - ✘ most recent proposals: combined algorithm (e.g., Compound TCP)
- ✘ Most important issues: operability and deployability

? Fairness ?

Motivation (cont'd)

- ✘ Number of fairness metrics proposed (e.g., Jain's index, proportional fairness, etc.)
- ✘ Common aspect: all concern with the
 - ✘ long term average of the flows
 - ✘ stable & equilibrium performance
- ✘ Can not capture *dynamic* properties!

Goals

- ✘ Fairness analysis of loss-based high speed TCPs
- ✘ focusing on dynamic behavior
- ✘ Reveal the impacts of short term dynamics on fairness
- ✘ Explanation of the phenomena
- ✘ Investigating
 - ✘ **MIMD** mechanism (Scalable TCP)
 - ✘ **AIMD-like** mechanisms (HighSpeed TCP, BIC TCP)

Methodology

- ✘ Ns-2 simulation environment
- ✘ Different topologies

✘ dumb-bell

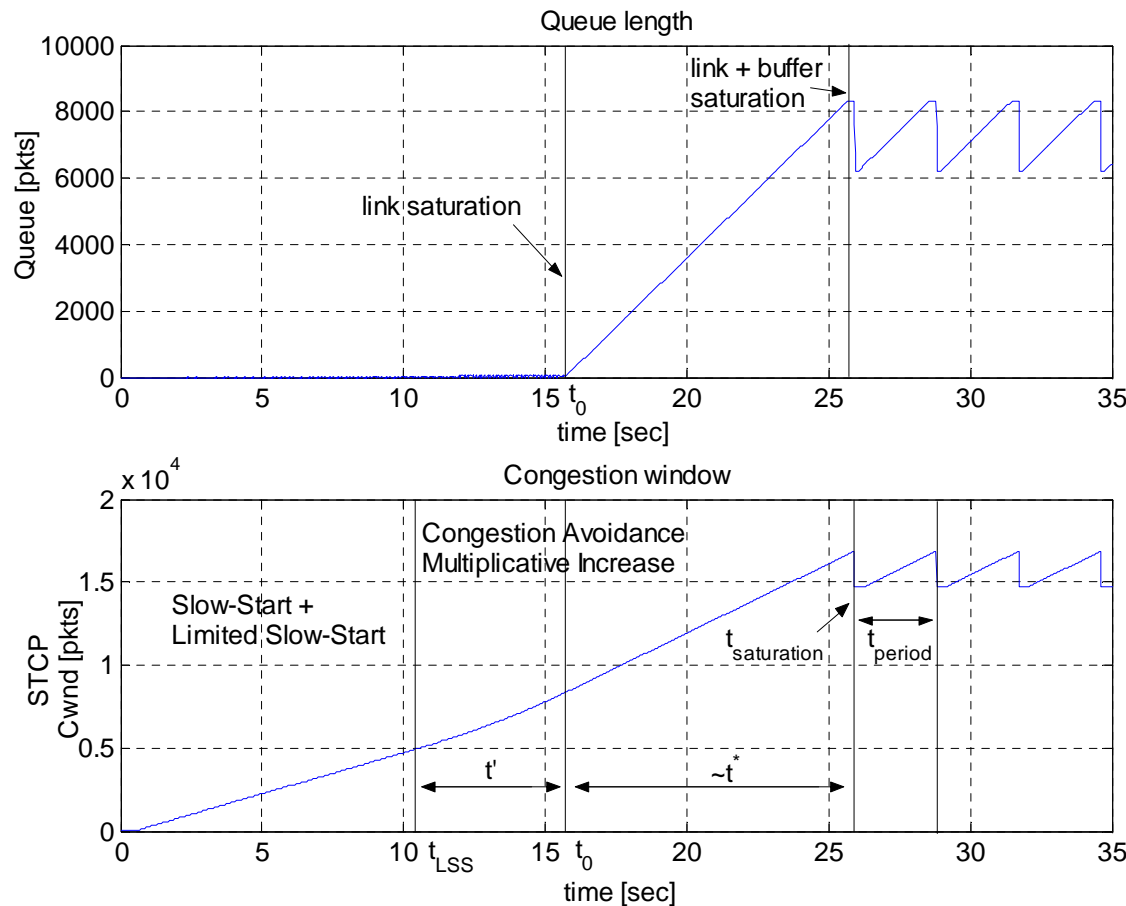

✘ simple parking-lot

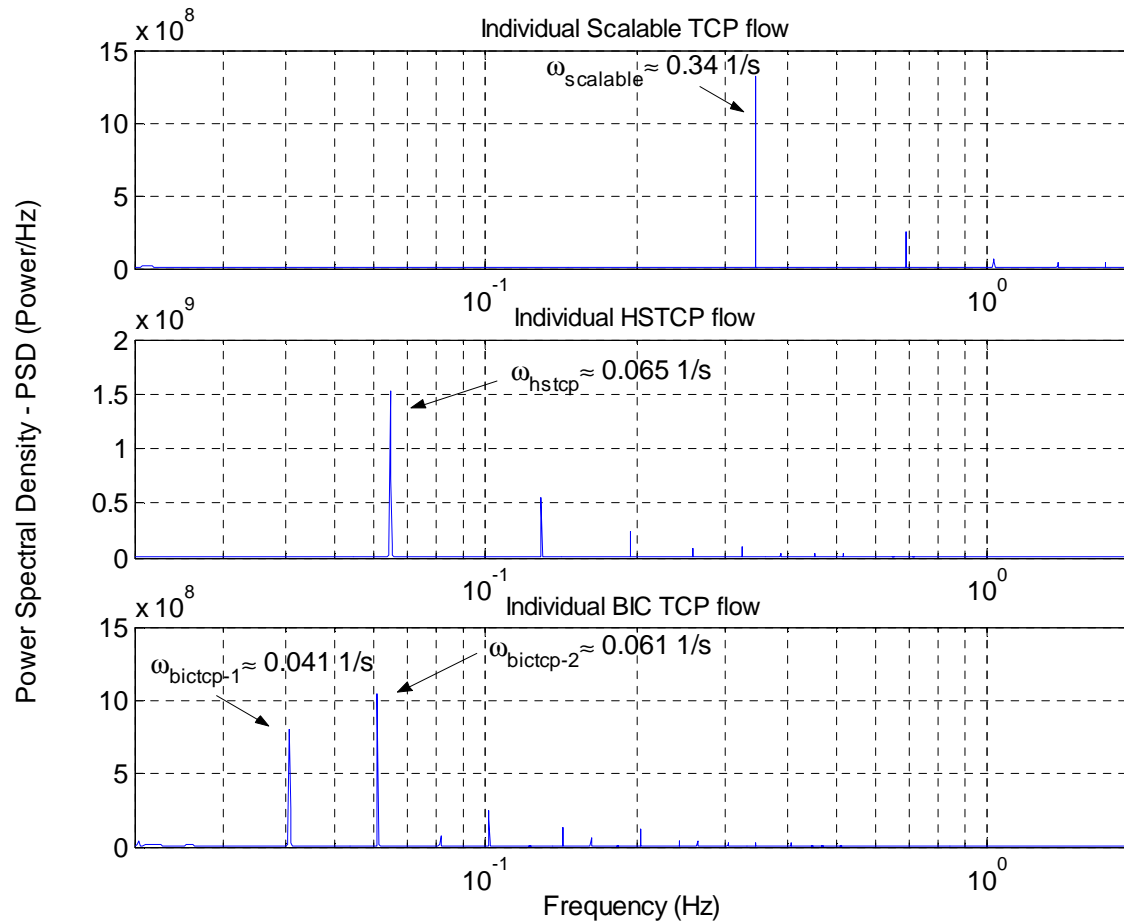

- ✘ Competition of high speed TCP flows
 - ✘ individual flows
 - ✘ single flow – traffic aggregate
- ✘ Dynamic behavior → different starting times

Initial behavior – saturation time of loss-based protocols

- ✗ Initial dynamics: significant role
- ✗ Saturation time
 - ✗ time till the first packet drop
 - ✗ can be derived analytically
- ✗ Example: STCP
 - ✗ Slow-Start
 - ✗ Limited Slow-Start
 - ✗ Multiplicative Increase
- ✗ After saturation time
 - ✗ periodic behavior
 - ✗ oscillation

Equilibrium behavior

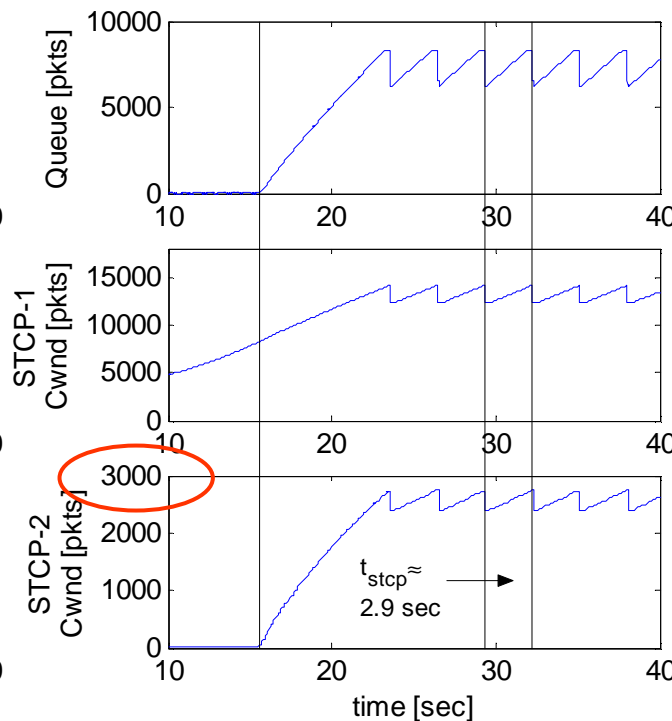

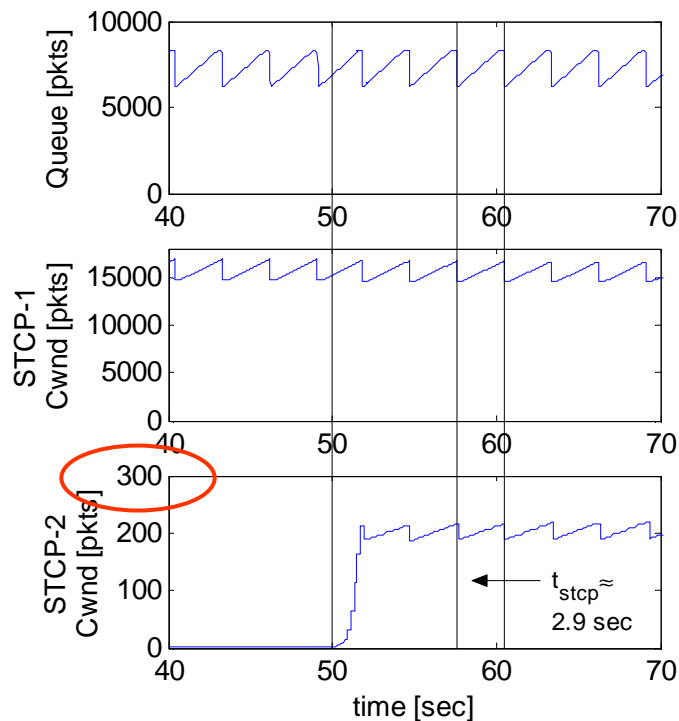

- ✘ Periodic behavior can be analyzed in the frequency domain
- ✘ main frequency spikes characterizing the equilibrium behavior
- ✘ significant differences

Intra-protocol behavior: MIMD

- ✘ Dumb-bell topology: two Scalable TCP flows
- ✘ Equilibrium behavior & fairness determined by starting time!

✘ delay: 50 sec

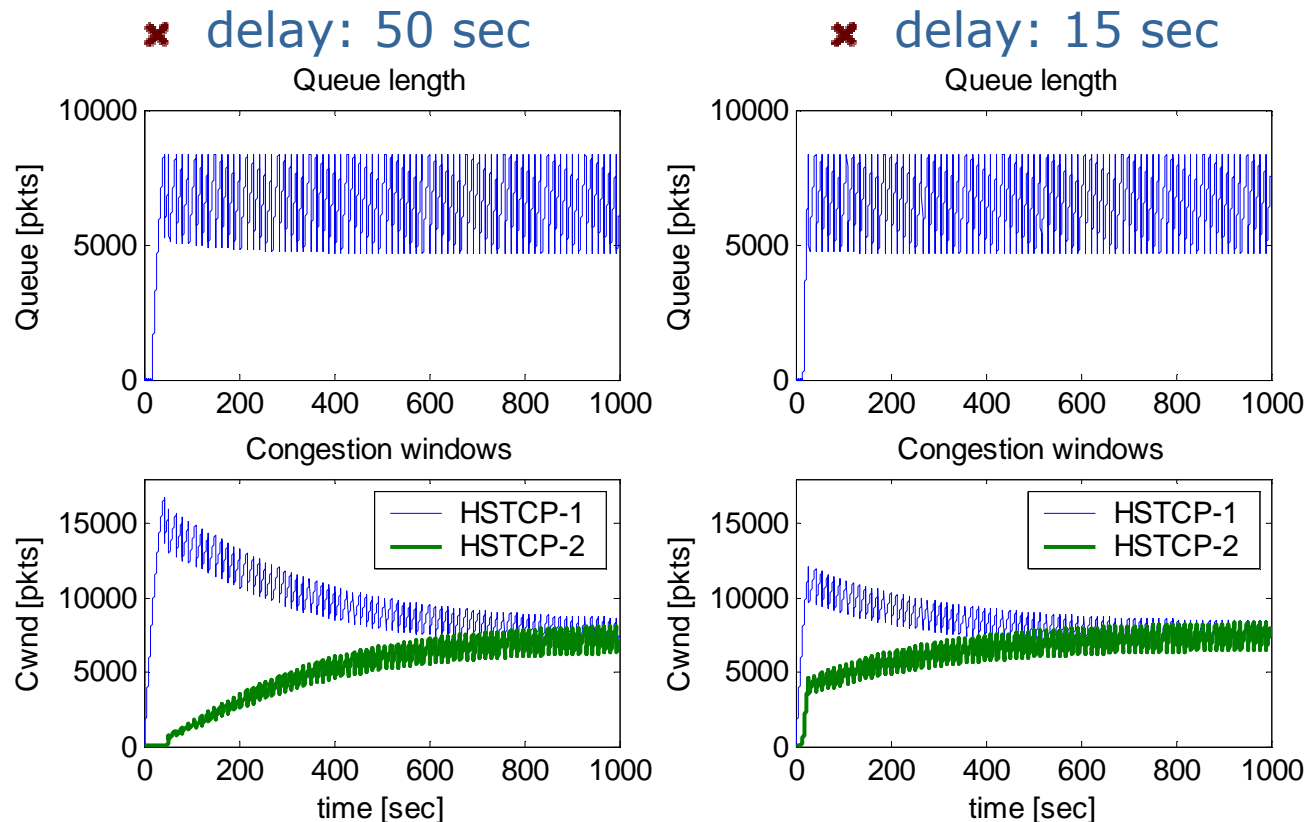

✘ delay: 15 sec

- ✘ MIMD mechanism → constant operating frequency
- ✘ Synchronized losses
- ✘ Equilibrium state depends on the length of the transient phase

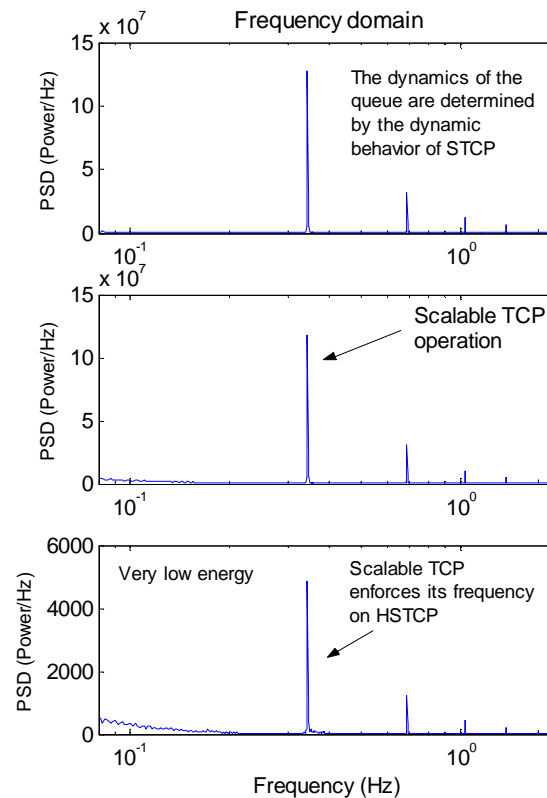

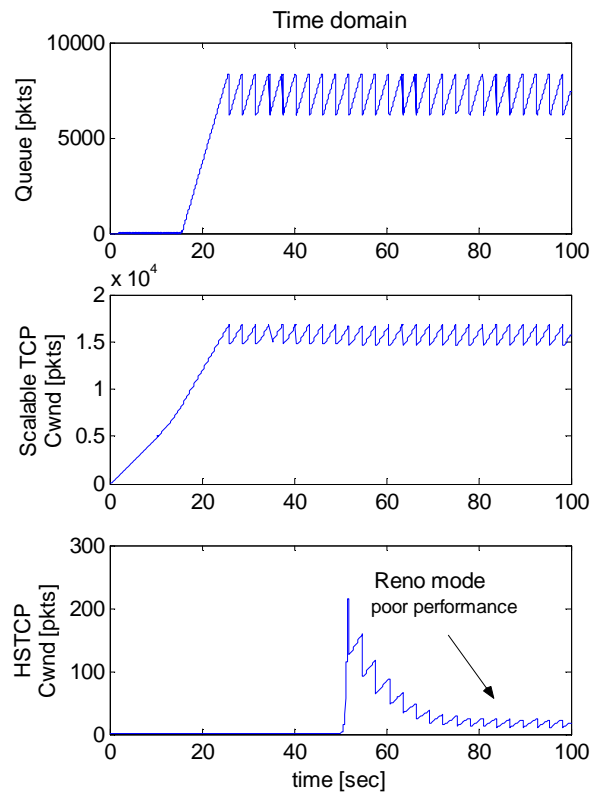

Intra-protocol behavior: AIMD

- ✘ Dumb-bell topology: two HSTCP flows
- ✘ Fair behavior, but transient phase can be too long!

Interaction of TCP versions (1)

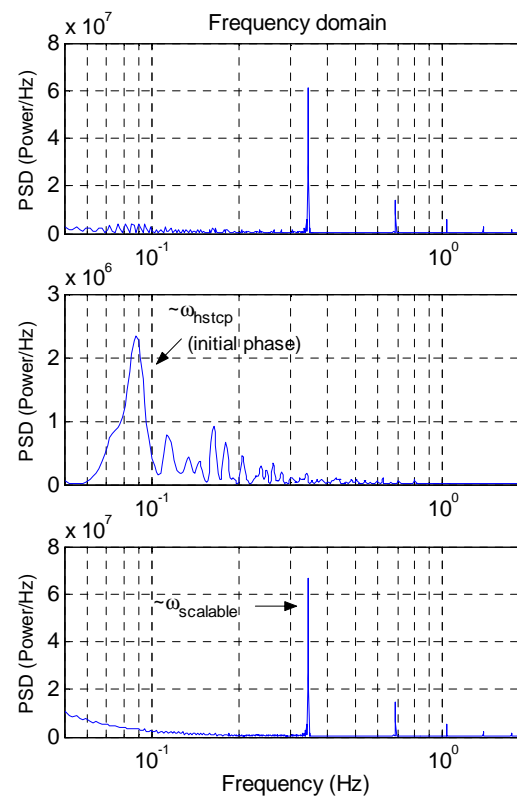

- ✘ Dumb-bell topology: Scalable TCP – HSTCP
- ✘ HSTCP enters later, **after** the **saturation time** of Scalable TCP

- ✘ **Starvation!**
- ✘ Synchronized losses
- ✘ Frequency is determined by Scalable TCP
- ✘ HSTCP
 - ✘ incr./period < decr.
 - ✘ decreasing trend
- ✘ Equilibrium:
 - ✘ cwnd < Low_W
 - ✘ TCP Reno operating mode
 - ✘ poor performance

Interaction of TCP versions (2)

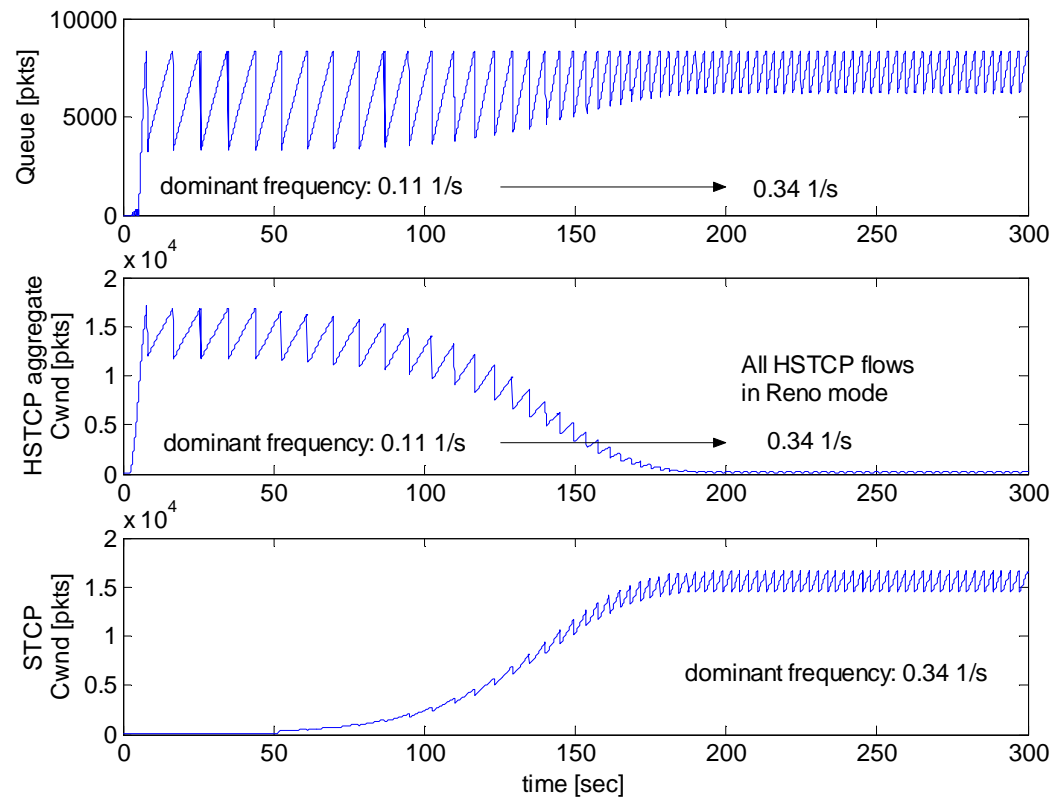

- ✘ Dumb-bell topology: Scalable TCP – HSTCP
- ✘ HSTCP enters first: better performance is expected ↔ but *starvation!*

- ✘ Interesting phenomenon
- ✘ Increasing frequency
- ✘ $\omega_{\text{hstcp}} \rightarrow \omega_{\text{scalable}}$
- ✘ Network behavior will be determined by Scalable TCP
- ✘ HSTCP converges to the same equilibrium state (TCP Reno operating mode)

Interaction of TCP versions (3)

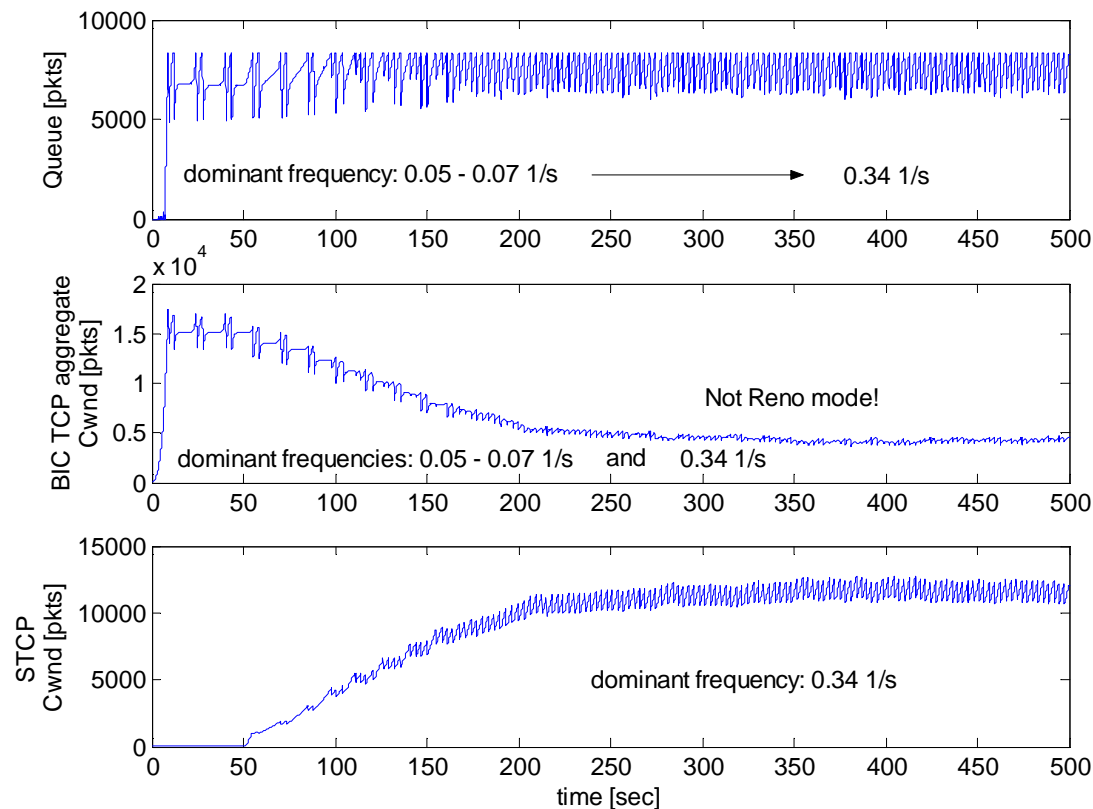

- ✘ Dumb-bell topology: HSTCP aggregate vs. single Scalable TCP flow
- ✘ 10 HSTCP flows and a later entering Scalable TCP

- ✘ Similar phenomenon
- ✘ Scalable TCP enforces its frequency on HSTCP aggregate
- ✘ All HSTCP flows fall back to Reno mode!

Interaction of TCP versions (4)

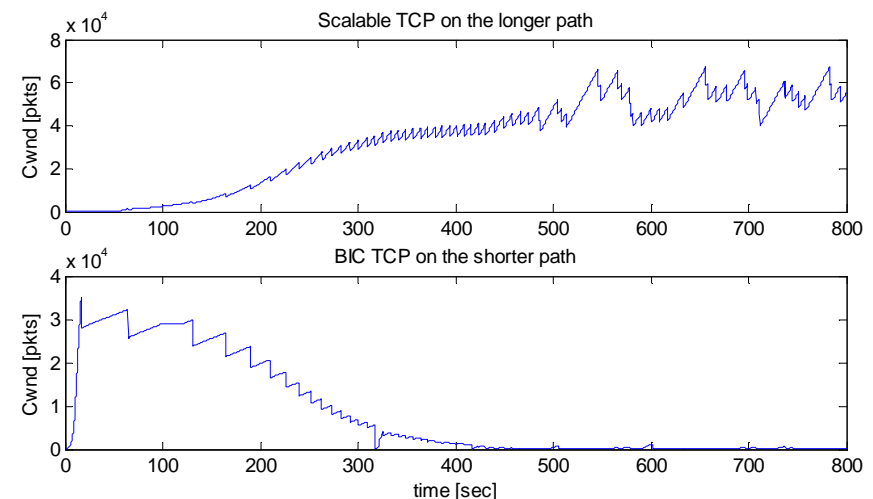

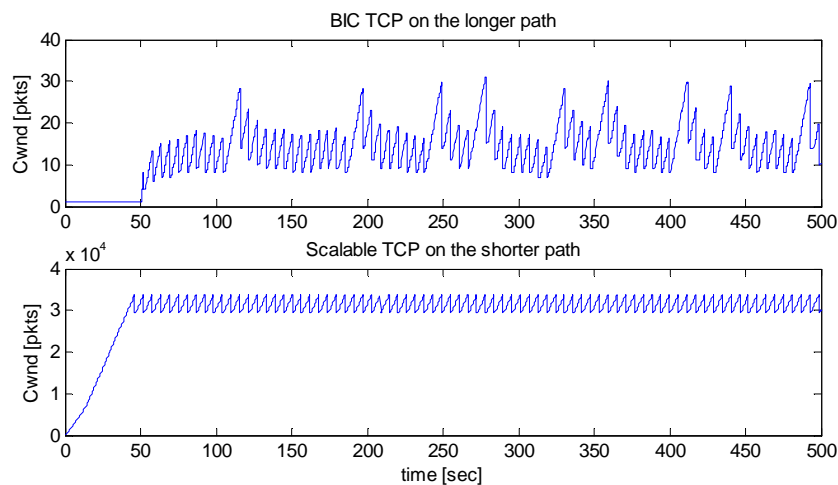

- ✘ Dumb-bell topology: BIC TCP aggregate vs. single Scalable TCP flow
- ✘ 10 BIC TCP flows and a later entering Scalable TCP

- ✘ Slightly better performance
- ✘ Not Reno mode!
- ✘ BIC TCP aggregate exhibits the dominant frequency of Scalable TCP as well
- ✘ Individual Scalable TCP flow dominates the network

Interaction of TCP versions (5)

- ✘ Simple parking-lot topology: single flows
- ✘ AIMD-like flow on the longer path
 - ✘ poor performance in all scenarios
 - ✘ Reno mode!
- ✘ MIMD flow on the longer path
 - ✘ Scalable TCP can push down the other flow
 - ✘ AIMD flow is always starved!

Summary of the results

- ✘ MIMD mechanism can not guarantee the fair behavior with AIMD-like protocols or other MIMD flows
- ✘ AIMD-like flows are starved in a wide range of network environments
- ✘ The intra-protocol behavior of MIMD mechanism is determined by the starting delay
- ✘ AIMD-like protocols are able to exhibit intra-protocol fairness
- ✘ but the transient phase can be very long

Conclusions

- ✘ Fairness analysis of loss-based high speed TCPs
- ✘ focusing on dynamic behavior
- ✘ Impacts of short term dynamics on fairness
- ✘ Explanation of the experienced phenomena

Thank You For Your Attention!

Simulation parameters

Network parameters

capacity	1 Gbps
RTT	100 ms
packet size	1,500 bytes

Bottleneck buffer size

dumb-bell	8,333 pkts
simple parking-lot	25,000 pkts

HSTCP parameters

Low_W	38
High_W	83,000
High_P	10^{-7}
High_Dec	0.1

Sampling periods

cwnd	0.01 sec
queue	0.01 sec
throughput	1 sec

BIC TCP parameters

beta	0.8
S_max	32
S_min	0.01
B	4

STCP parameters

a	0.01
b	0.125

Motivation (cont'd)

Performance of two competing Scalable TCP flows
